## A NEW LARVA OF THE GENUS *LEPTUS* LATREILLE, 1796 (ACARI: ERYTHRAEIDAE) PARASITIC ON A SPIDER FROM RWANDA

A. Fain<sup>1</sup> and R. Jocqué<sup>2</sup>

1. Institut royal des Sciences naturelles de Belgique, rue Vautier 29, B-1040 Bruxelles, Belgium. 2. Musée royal de l'Afrique centrale, B-3080 Tervuren, Belgium. Fax- 32-2-646-4433.

**SUMMARY** -The larva of *Leptus rwandae* n. sp. (Acari: Erythraeidae) is described from a spider, *Systemoplacis* sp. (Zodariidae), from Rwanda. A list of the mite species recorded from spiders throughout the world is provided. (Key words: Taxonomy. Larva. *Leptus*. Acari -Erythraeidae. Acari parasitic. Araneae.)

**RÉSUMÉ** - La larve de *Leptus rwandae* n. sp. (Acari: Erythraeidae), est décrite; elle avait été récoltée sur une Araignée, *Systemoplacis* sp. (Zodariidae), du Rwanda. Une liste de toutes les espèces d'acariens signalées jusqu'ici sur les Araignées dans le monde, est donnée. (Mots clé: Taxonomie. Larve. *Leptus*. Acari -Erythraeidae. Parasite. Araneae.)

### INTRODUCTION

Until now, five species of larval *Leptus* (Acari: Erythraeidae) have been described from spiders, two of which are from Japan and three from the U.S.A., South Africa and England, respectively. A list of these species has been provided by Welbourn and Young (1988).

We describe here the larva of a new species of *Leptus* collected by R. J. on a spider, *Systemoplacis* sp. (Zodariidae), from Rwanda. The holotype is deposited in the Museum de l'Afrique Centrale, Tervuren. A list of all the mite species reported from spiders is given.

The measurements used here are in micrometers ( $\mu\text{m}$ ). Standard data follows Southcott (1961, 1988 and 1992) except for the measurements of the solenidia (see Table I).

### Remarks on some characters in the genus *Leptus*

1. **The term ASBM** - Fain and Elsen (1987) introduced a new measurement (ASBM) to the metric data proposed by Southcott (1961). The ASBM was defined as follows: "La distance entre la base des sensillas antérieures et le bord antérieur du scutum sur la ligne médiane" (= distance between the centers of anterior sensilla and the anterior border of the scutum on the median line). This measurement provided a good estimation of the cur-

vature of the anterior border of the scutum. Southcott (1988 and subsequent papers) adopted this new character but he misinterpreted the original definition given by Fain *et al.* He defined ASBM as the "distance between anterior end of dorsal scutum to centre of anterior edge of scutum" (Southcott, 1992). These definitions are not identical and the new definition leads to confusion. It is, however, possible to calculate the distance ASBM *sensu* Fain and Elsen (1987) by the following operation: ASBM = ASBa - ASBM *sensu* Southcott.

2. **Famulus of tibia I** - Fain (1992) suggested that in the trombidiids the short seta situated on tibia I close to the apical solenidion is a famulus ( $\epsilon$ ) and not a simple seta  $\kappa$ . We think now that this famulus is also present in the Erythraeidae, particularly in the genus *Leptus*. This short seta is homologous with the famulus of tibia I described by Grandjean (1938) in the Tydeidae, Ereynetidae and Eupodidae. According to this author: "Le petit poil du tibia I est remarquable par sa constance. J'ai fait observer qu'il existe toujours dès la larve. Corrélativement il ne manque jamais chez les Tydeidae, et même, d'après les espèces que j'ai vues, chez les Ereynetidae et les Eupodiidae. On se tromperait donc fortement si l'on assimilait ce poil à un poil ordinaire dont la taille s'amoindrit et qui serait sur le point de disparaître. Il vaut mieux le comparer à un famulus" (Grandjean, 1938: p. 599, Figs. 1-2).

Fain (1985) showed that this small seta is present in all the species and in all the stages (larva, nymph and adults) of Ereynetidae. In this family, this famulus is always closely associated with the apico-dorsal solenidion of tibia I and forms part of the "ereynetal organ" (Fain and Camerik, 1994).

3. **Solenidia of legs in the genus *Leptus*** - Tibia I bears 2 solenidia (rarely more):  $\varphi Ia$  (apical) and  $\varphi Ib$  (slightly more basal); the most apical is flanked by a famulus  $\epsilon$ . Tibia II also bears two solenidia an apical ( $\varphi IIa$ ) and a basal ( $\varphi IIb$ ). Tibia III has one basal solenidion ( $\varphi III$ ) as does genu I ( $\sigma$ ).

### *Leptus rwandae* nov. spec.

**Larva**, holotype (Figs. 1-9) - Standard data given in Table I. Length of idiosoma 295, width 195. In the paratype 270 × 160. **Dorsum** - scutum distinctly wider than long, ratio length: width = 0.8 in holotype and 0.74 in paratype. There are 50 thickly barbed setae behind the scutum. **Venter** - with 2 pairs of setae between coxae II and III set on a transverse line. Opisthogaster with 20 barbed setae. **Gnathosoma** - genu and femur of palps with

1 barbed seta each. Tarsus with 2 solenidia (1 basal and 1 apical) and 5 pectinate and 1 smooth thin setae. Legs (number of normal setae): Trochanters 1-1-1; Femora 7-7-6; Genua 8-8-8; Tibia 13-13-15. Tarsi I and II each with 2 eupathidia. Tarsus III with 1 eupathidia.

**Status of *Leptus rwandae*** - This new species resemble superficially *L. galerucae* Feider, 1967. It is, however, distinct from this species in the following characters: Scutum much smaller, AL, PL and leg segments much shorter (see metric data of *L. galerucae* in Southcott, 1992).

*L. rwandae* is closer to *L. cavernicola* Fain and Elsen, 1987, described from a cave in Rwanda. It is distinguished from this species by several characters (see Table I): scutum distinctly wider than long (ratio L × W = 0.8, instead of 1.04 in *L. cavernicola*); setae 'Oc' much shorter, AW and PW longer, PL shorter, some leg segments (TiIII and FeIII) distinctly shorter, StI, StII and  $\varphi IIa$  about twice shorter,  $\omega I$  and  $\omega II$  strongly unequal (equal in *L. cavernicola*); the four setae located between coxae II and III placed along a single transverse row (these setae form two transverse rows in *L. cavernicola*).

A third species, *L. atticus* Lawrence (1940), described from a spider, *Saitis* sp. (Salticidae), from Natal,

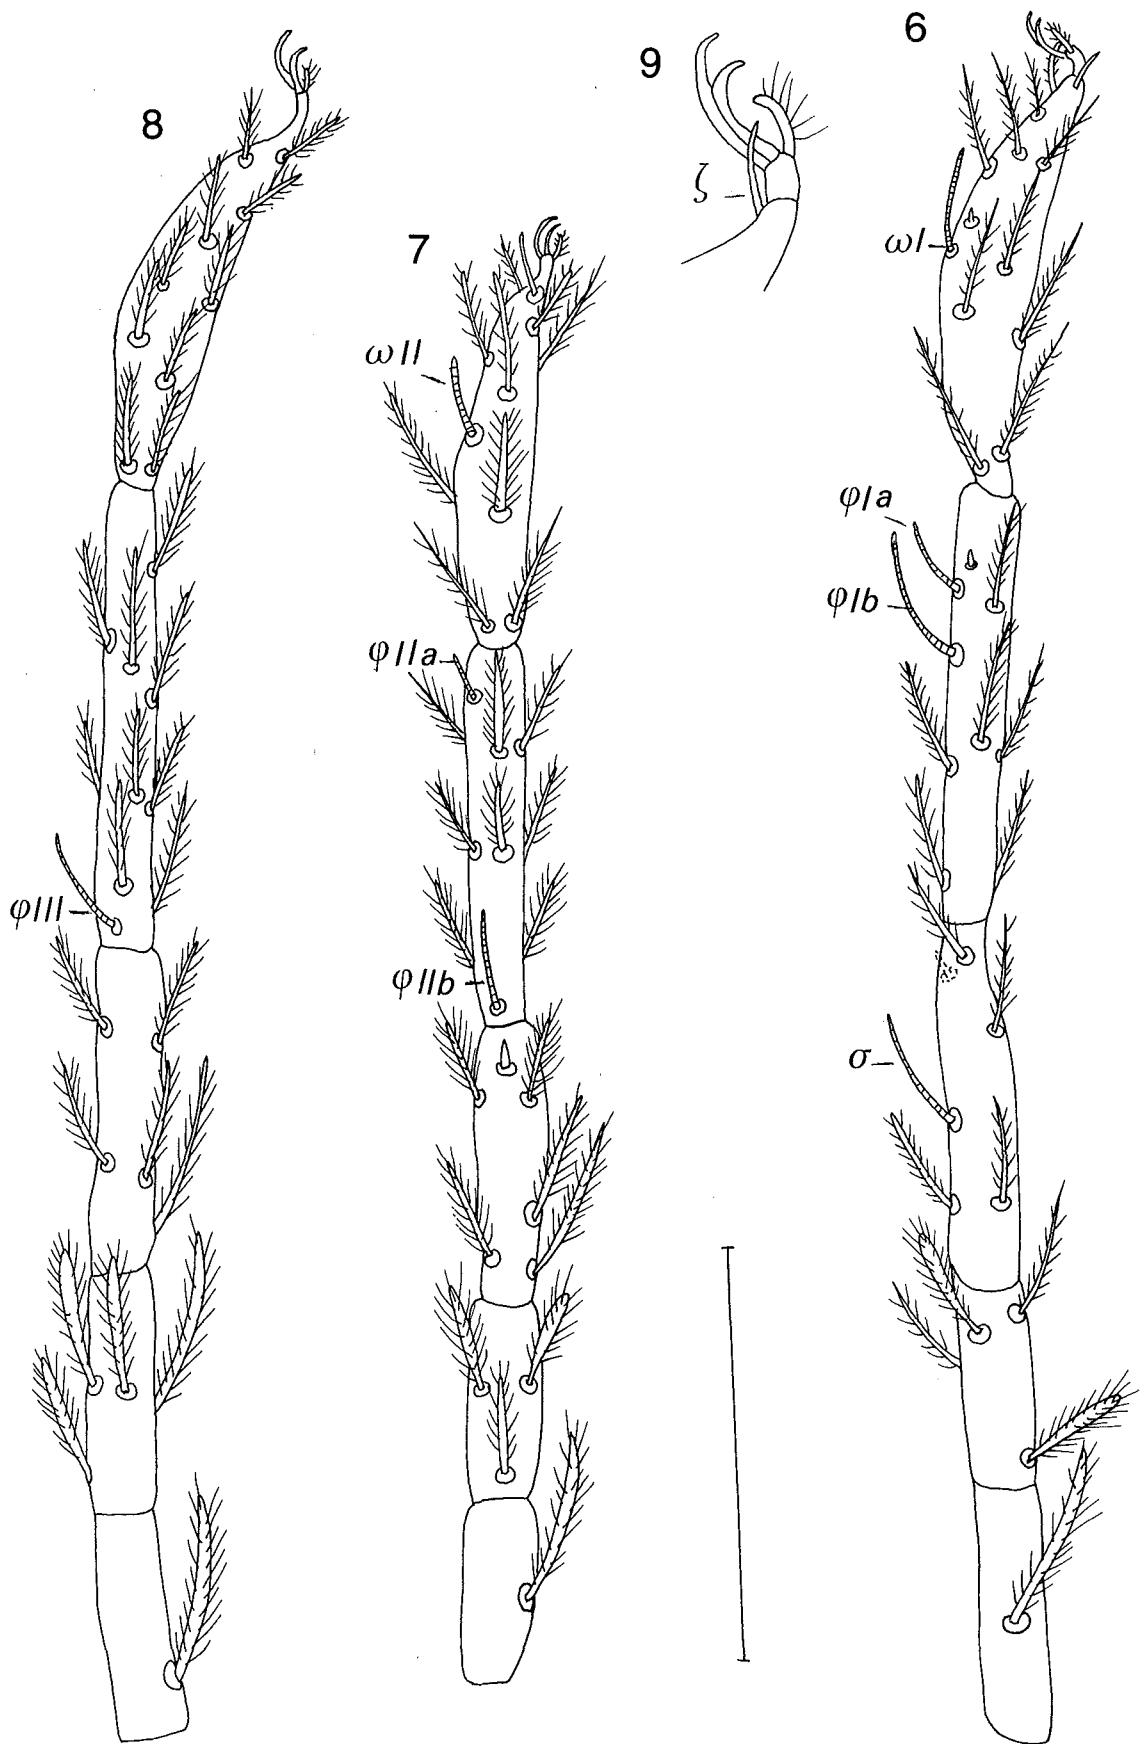

Table I. Metric data of the larvae of *Leptus atticus* Lawrence, *L. cavernicola* Fain and *L. rwandae* n. sp.

Remark - The symbol ASBM is that proposed by Fain & Elsen (1987).

also resembles our species. Through the kindness of Dr. Michelle Hamer, Curator of Arthropod Studies, Museum of Natal, we examined the holotype of this species. This specimen is labelled "*Leptus atticolus* Law. Typus Nm 1239". In addition to the holotype we also received 3 paratypes from the same host and 4 larvae from *Rhamsinitis fissidens* (an Opilion) and assigned by Lawrence to the same species. All these specimens in liquid preservative are strongly macerated and very transparent. We can notice, however, that they resemble very closely the holotype of *L. atticolus* by the lengths of the legs, the number and length of the idiosomal setae and the metric data of the shield. In a paratype the AL is 48, the PL 50 to 60,

and the tarsus III 120 long.

The holotype of *L. atticolus* is strongly flattened but most of the characters are still recognizable. The sensillae and PL are lost or incomplete. There are 2 pairs of setae between coxae II and III, a medial pair more posterior than the lateral pair. Number of idiosomal setae difficult to count with certainty. There are about 25 to 30 dorsal pairs and 10 to 13 pairs of opisthogastric setae. Distance between  $\varphi Ia$  and  $\varphi Ib$  27;  $\omega I$  and  $\omega II$  are inserted in the apical half of the tarsi. Table I gives the metric data. In *L. atticolus* the legs are significantly longer than in *L. cavernicola* and *L. rwandae*.

Finnegan (1933) described a new mite *Copriphis (Pelethiphis) bristowi* (or ? *bristowei*) Finnegan from a spider, *Liphistius malayanus*, from Malaysia. Welbourn and Young (1988) assumed that these mites more likely belong to the genus *Ljunghia* Oudemans.

We have reexamined the types of this species. They are in very poor condition and it is not possible to ascertain that they belong to the genus *Ljunghia*. The type male has a very long sternigenital shield which is fused with the anal shield. In the males of the five species of *Ljunghia* (*selenocosmiae*, *pulleinei*, *hoggi*, *minor* and *novecaledoniae*) that we have examined, the sternigenital shield is short and remains far from the anal shield. We think, therefore, that the species of Finnegan does not belong to the genus *Ljunghia*.

#### ACKNOWLEDGEMENTS

We thank Dr. Michelle Hamer, Curator of the Department of Arthropod Studies, Natal Museum, South Africa, for the loan of the type of *Leptus atticolus* Lawrence. We also are grateful to Dr. Ann Baker, Department of Acarology, Museum of Natural History, London, who sent us the types of *Copriphis (Pelethiphis) bristowi* Finnegan for our study.
